Milestone in semiconductor development

New semiconductor material: AIYN promises more energy-efficient and powerful electronics

Researchers at Fraunhofer IAF have made a breakthrough in the field of semiconductor materials: With aluminum yttrium nitride (AIYN), they have succeeded in fabricating and characterizing a new and promising semiconductor material using the MOCVD process. Due to its excellent material properties and its adaptability to gallium nitride (GaN), AIYN has enormous potential for use in energy-efficient high-frequency and high-performance electronics for information and communications technology.

Aluminum Yttrium Nitride (AIYN) has attracted the interest of many research groups around the world due to its outstanding material properties. However, the growth of the material has been a major challenge. Until now, AIYN could only be deposited by magnetron sputtering. Researchers at the Fraunhofer Institute for Applied Solid State Physics IAF have now succeeded in fabricating the new material using metal-organic chemical vapor deposition (MOCVD) technology, thus enabling the development of new, diverse applications.

"Our research represents a milestone in the development of new semiconductor structures. AIYN is a material that enables increased performance while minimizing energy consumption, paving the way for innovations in electronics that our digitally connected society and its ever-increasing technology demands urgently need," says Dr. Stefano Leone, scientist at Fraunhofer IAF in the field of epitaxy. With its promising material properties, AIYN could become a key material for future technological innovations.

Recent research had already demonstrated the material properties of AlYN, such as ferroelectricity. In developing the new compound semiconductor, the researchers at Fraunhofer IAF focused primarily on its adaptability to gallium nitride (GaN): The lattice structure of AlYN can be optimally adapted to GaN and the AlYN/GaN heterostructure promises significant advantages for the development of future-oriented electronics.

From layer to heterostructure

In 2023, the Fraunhofer IAF research group achieved groundbreaking results when it succeeded in depositing a 600 nm thick AIYN layer for the first time. The layer with wurtzite structure contained an unprecedented yttrium concentration of more than 30 percent. Now the researchers have achieved another breakthrough: they have fabricated AIYN/GaN heterostructures with a precisely adjustable yttrium concentration, which are characterized by excellent structural quality and electrical properties. The novel heterostructures have an yttrium concentration of up to 16 percent. The structural analysis group, led by Dr. Lutz Kirste, continues to perform detailed analyses to further the understanding of the structural and chemical properties of AIYN.

The Fraunhofer researchers have already measured very promising electrical properties of AIYN that are of interest for use in electronic components. "We were able to observe impressive values for sheet resistance, electron density and electron mobility. These results showed us the potential of AIYN for high-frequency and high-performance electronics," Leone reports.

AlYN/GaN heterostructures for high-frequency applications

Due to its wurtzite crystal structure, AIYN can be adapted very well to the wurtzite structure of gallium nitride with a suitable composition. An AIYN/GaN heterostructure promises to enable the development of semiconductor components with improved performance and reliability. In addition, AIYN has the ability to induce a two-dimensional electron gas (2DEG) in heterostructures. Recent research results from Fraunhofer IAF show optimal 2DEG properties in AIYN/GaN heterostructures at an yttrium concentration of about 8 percent.

The material characterization results also show that AIYN can be used in high electron mobility transistors (HEMTs). The researchers observed a significant increase in electron mobility at low temperatures (more than 3000 cm²/Vs at 7 K). The team has already made significant progress in demonstrating the epitaxial heterostructure required for fabrication, and continues to explore the new semiconductor for the development of HEMTs.

The researchers are also optimistic about industrial applications: Using AlYN/GaN heterostructures grown on 4-inch SiC substrates, they demonstrated the scalability and structural uniformity of the heterostructures. The successful creation of AlYN layers in a commercial MOCVD reactor enables scaling up to larger substrates in larger MOCVD reactors. This method is considered the most productive for the fabrication of large-area

semiconductor structures and underlines the potential of AIYN for the mass production of semiconductor devices.

Development of non-volatile memories

Due to its ferroelectric properties, AIYN is highly suitable for the development of nonvolatile memory applications. Another important advantage is that the material has no limitation on layer thickness. Therefore, the research team at Fraunhofer IAF encourages further research into the properties of AIYN layers for non-volatile memories, as AIYNbased memories can drive sustainable and energy-efficient data storage solutions. This is particularly relevant for data centers, which have to cope with the exponential growth in computing capacity for artificial intelligence and have significantly higher energy consumption.

The challenge of oxidation

A major obstacle to the industrial use of AIYN is its susceptibility to oxidation, which affects its suitability for certain electronic applications. "In the future, it will be important to explore strategies to reduce or overcome oxidation. The development of high-purity precursors, the use of protective coatings, or innovative manufacturing techniques could contribute to this. The susceptibility of AIYN to oxidation is a major research challenge to ensure that research efforts are focused on areas with the greatest chance of success," concludes Leone.

About Fraunhofer IAF

The Fraunhofer Institute for Applied Solid State Physics IAF is one of the world's leading research institutions in the fields of III-V semiconductors and synthetic diamond. Based on these materials, Fraunhofer IAF develops components for future-oriented technologies, such as electronic circuits for innovative communication and mobility solutions, laser systems for real-time spectroscopy, novel hardware components for quantum computing as well as quantum sensors for industrial applications. With its research and development, the Freiburg research institute covers the entire value chain — from materials research, design and processing to modules, systems and demonstrators.

The **Fraunhofer-Gesellschaft**, based in Germany, is one of the world's leading applied research organizations. It plays a crucial role in the innovation process by prioritizing research in key future technologies and transferring its research findings to industry in order to strengthen Germany as a hub of industrial activity as well as for the benefit of society.

Founded in 1949, the Fraunhofer-Gesellschaft currently operates 76 institutes and research units throughout Germany. Its nearly 32,000 employees, predominantly scientists and engineers, work with an annual business volume of 3.4 billion euros; 3.0 billion euros of this stems from contract research, which is divided into three funding pillars. Fraunhofer generates a share of this from industry and license-fee revenue, totaling 836 million euros. This high proportion of industrial revenue is Fraunhofer's unique selling point in the German research landscape. Another share of contract research revenue comes from publicly funded research projects. The final share is base funding supplied by the German federal and state governments and enables our institutes to develop solutions now that will become relevant to the private sector and society in a few years.
